

# ADVERSARIA: A SPECIFICATION FOR A PUBLIC CLAIM GRAPH

MOVING FROM PAGES AND TRIPLES TO ARGUED PROPOSITIONS.

# The Gluing Failure of Modern Encyclopedias

|                        | The Page<br>(Wikipedia)            | The Statement Store<br>(Wikidata) | Argued Proposition<br>(Adversaria) |
|------------------------|------------------------------------|-----------------------------------|------------------------------------|
| Scope                  | Implicit in prose                  | Optional qualifiers               | Mandatory,<br>region-valued        |
| Conflict<br>Resolution | Editorial dispute<br>(hedged text) | Scalar ranks<br>(one winner)      | Localized to<br>overlapping scope  |
| What Fails             | The page is<br>rewritten           | The value is<br>deleted           | A precise component<br>is attacked |

The page is an **excellent unit for reading**, but a **structurally broken unit for adjudication**. It forces a **single narrative on overlapping truths**.

# The Anatomy of an Argued Proposition

Adversaria does not store what is true. It stores what is claimed, the scope it covers, why it might be true, and what would make it fail.

## Epistemic Modality

Is this descriptive, causal, or normative?

## The Core (Kernel + Scope)

The exact proposition asserted, and the specific unit space where it applies.

## Provenance & Version

Immutable hashes linking to the append-only ledger.

# Truth is Regional, Not Global

**Scope Monotonicity:**  
Narrowing a scope never breaks a valid claim.

**Localized Conflict:**  
Two claims never contradict one another globally.

Conflict strictly exists on the exact geometric intersection of their scopes.

Contradiction does not explode the system. It merely defines a boundary.

# The Bridging Warrant

Evidence does not speak for itself. A dataset does not automatically prove a causal claim.

Most epistemic disagreements do not happen over the data itself. They happen **over the bridge**. Adversaria makes this bridge explicit, scoped, and attackable.

# Objections as Structural Attacks

An objection is not a comment on a page. It is a formal argument that denies a specific structural target within an existing claim. Keeping these failure modes mathematically distinct allows the graph to precisely locate where consensus breaks down.

# Constraint as Region Removal

Most scholarship doesn't completely refute a claim; it limits its boundaries.

The system does not delete the challenged claim. It automatically computes the survivor—the largest remaining region that is undefeated throughout.

# Volume Does Not Equal Consensus

In an era of Generative AI, volume can spoof agreement. Adversaria groups evidence by Independence Families, not record counts.

10,000 Raw Data Inputs

Ten thousand automated agents repeating one inference constitute **one dependent lineage**, not ten thousand independent confirmations. Truth cannot be brute-forced by volume.

# The Status Vector: Rejecting Scalar Scores

A single truth score forces invisible tradeoffs and hides fatal flaws. Adversaria refuses to collapse epistemic standing into one number.

Popularity is isolated.

Agreement is tracked,  
but has zero defeat  
power in the graph.

Votes cannot  
overturn warrants.

# Diagnosing Disagreement

A generic disputed tag blurs reality. The Status Vector explicitly diagnoses the epistemic state.

|                                                                                     |                          |                                                                                                                                                |                                                                           |
|-------------------------------------------------------------------------------------|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------|
|    | Lack of Evidence         | State: <b>N</b>                                             | No argument present                                                       |
|   | Balanced Conflict        | State: <b>B</b>                                            | Mutual rebuttal,<br>no tiebreaker                                         |
|  | Methodological<br>Attack | State: <b>T</b> or <b>F</b>                               | Warrant is contested<br>by an undercutter                                 |
|  | Scope Mismatch           | State: <b>T</b> in one<br>region,<br><b>F</b> in another  | Pro and con arguments<br>exist, but their scopes are<br>entirely disjoint |

# Fixing the Glue: Ontologies & Distinction

When communities violently disagree, they are often using the same word for two different constructs.

Emotional Differentiation  
(Overloaded Term)

Pooling Declaration

Sense A: Within-Person Granularity

Sense B: Self-Report Score

A Pooling Declaration splits an overloaded term into distinct senses. The conflicting claims safely bypass each other, occupying different ontological spaces. The dispute is resolved by mapping, not by editing.

# The Architecture of Truth

## Layer 3: Dossier

What stands  
(Policy-Relative  
Consensus)

## Layer 2: Graph

What follows  
(Structural Logic)

## Layer 2: Graph

What follows  
(Structural Logic)

## Layer 1: Record

What happened  
(Traces & Acts)

# Policy-Relative Projection

Different communities can share the exact same ledger of facts, but arrive at different conclusions based on their stated Policies (preferences on evidence weight, methodology, or rung ladders).

Disagreement between communities is mathematically located in the policy, not hidden in the database.

# Routing vs. Adjudication

Social media conflates attention with truth. Adversaria severs this link.

Relevance to a reader does not establish support. Support does not establish relevance. A claim routed to a million feeds is not epistemically stronger than a claim routed to ten.

# A New Epistemic Constitution

Adversaria assumes bad actors, automated spam, and deep philosophical disagreements—and creates a resilient geometry for them to coexist without systemic explosion.

1. Record traces, not intentions.
2. Compute standing, never edit history.
3. Measure vectors, reject scalar scores.
