

The Public Claim Graph

An architecture for computing honest disagreement.

Moving beyond pages and statements to map the exact contours of human knowledge.

Prose Hides the Architecture of Conflict

The Illusion

The Reality

Core Insight: When knowledge is stored as prose, **conflicts** live between pages—invisible to editors and uncomputable by machines.

The Root Cause: Choosing the Wrong Unit

	The Page	The Statement	The Argued Proposition
Payload	Prose	Subject / Property / Value	Claim + Scope + Grounds + Warrant + Objections
Conflict Handling	Editorial dispute / hedged wording	Two values ranked or deleted	Localized to the exact overlap of scopes
Failure Mode	Whole page edited	Value deprecated	Only the attacked component fails; a narrower claim survives

Takeaway Callout: Pages cannot compute overlap. Statements cannot record warrants. Argued Propositions localize conflict exactly where scopes intersect.

Anatomy of the Argued Proposition

Disagreement is rarely a simple contradiction. A discrete structure allows us to pinpoint exactly where an argument fails.

Mapping the Topology of Conflict

Key Rule Box: A claim graph tells us exactly why two sides collide, replacing endless debate with specific structural diagnoses.

Redefining the “Null” Result

Null Detection

The test failed to detect.
(Opposes nothing alone;
requires a further warrant)

Bounded Effect

Design proved smallness.
(Supports negation directly)

Opposite Effect

Found reverse correlation.
(Supports negation by entailment)

Failed Replication

Attempt failed.
(Adds to a count, but is not
evidence for a claim)

A failed search is not proof of absence without an explicit, attackable warrant.
The system evaluates a bounded effect exactly as strongly as a positive finding.

Standing is a Vector, Not a Score

Score hides tradeoffs & invites gaming

Any single scalar score forces a hidden exchange rate. A vector reveals the Frontier—the set of claims that are undominated across all dimensions.

The Danger of Proxy Drift: Routing $\neq$ Adjudication

Security Invariant: Every non-standing argument can be made to look standing if a view hides its defeaters. Status must always be computed on the full active set.

The Two-Plane Protocol

Core Principle

The Authorization Plane decides who can modify a shared projection. The Argument Plane computes what stands. Authority never enters the defeat graph.

Inscription vs. Authority

Open Inscription

Governed Projection

Insight Bar

The freedom to inscribe is not the same as the authority to modify a shared projection.
A capability allows admission; it confers no standing for the conclusion.

Securing Time: Ledger vs. Claimed Time

A contributor can control when they submit, but the anchor chain strictly governs the sequence. Revocations are always prospective; history cannot be silently rewritten.

Restrictions and the Meta-Surface

[Security Invariant]

If a restriction were evaluated on the surface it restricts, it could gate the very objections that would defeat it. Restrictions must be justified by arguments on an unrestricted meta-surface.

Proof Objects & The Closure Certificate

[Takeaway Callout]

A display is only as good as its proof of completeness. Readers locally verify a label by checking that the backward closure of the argument matches the anchor's cryptographic commitment.

The Anti-Capture Invariants

Validation

Inscription is open; Capabilities are explicit.

Structure

Gates test competence, not belief (Position-Neutrality).

Computation

Reasons for refusal are deterministic; statistics are auditable.

Insight Box

The design does not make human authority disappear, nor does it make it wise.
It makes it visible, bounded, and rigorously contestable.

A Topology of Knowledge

A shared knowledge base cannot—and should not—declare absolute truth. By adopting the Argued Proposition, we build an epistemic ledger that computes exactly where we stand, why we disagree, and what it would take to change our minds.
